SUPERCONVERGENT RECOVERY OF THE GRADIENT FROM PIECEWISE LINEAR FINITE ELEMENT APPROXIMATIONS

Nick Levine

ABSTRACT

We propose and justify the use of a simple scheme which recovers gradients from the piecewise linear finite element approximation on triangular elements to the solution of a second order elliptic problem. The recovered gradient is a superconvergent estimate of the true gradient at the midpoints of element edges. A related scheme recovers the gradient at the element centroids.
1. **INTRODUCTION**

For quadrilateral elements, gradient superconvergence has been well established since Veryard (1971) improved the accuracy of the gradients of biquadratic Galerkin approximations by sampling them at the second order Gauss points in each element. Such points of exceptional accuracy of derivatives of finite element approximations have come to be known as "stress points" and their existence as an example of the phenomenon of "superconvergence"; we associate these terms here with the sampling or recovery of gradients to one order of accuracy higher than is globally possible.

Stress points are located (Strang & Fix, 1973, pp. 168-9; Barlow, 1976) by the property that the derivative of the polynomial which dominates the error expansion coincides with its approximation (i.e., the derivative of a lower-degree polynomial). This idea is at the heart of any superconvergence result, for it leads us directly to the stress points of the "unknown" function's interpolant. Further, the gradient of the interpolant is at all points a superconvergent approximation to the gradient of the finite element solution. Therefore the stress points for these two functions are identical. (For proofs of this result on quadrilateral elements, see Zlámal, 1977, 1978 and LeSaint & Zlámal, 1979).

It has been suggested (e.g., Moan, 1974) that the Galerkin least-squares approximation to gradients is "almost local" and can therefore be analysed in one element in complete isolation from all others. Although this reasoning is fortuitously successful for quadrilaterals it fails on linear triangles, for it implies that their centroids are stress points. On the other hand the interpolant method given above predicts for these elements that "midpoints of an (element) edge seem ... to be exceptional for derivatives along the edge but not for stresses in the direction of the normal". (Strang & Fix, 1973, p. 169).

In this paper we consider piecewise linear approximations on triangular elements to a model Dirichlet problem. We prove (in section 3) that element edge midpoints are indeed tangential derivative stress points for the interpolant
and complete the above outline by returning to the finite element method in sections 4 and 5. We must however impose the following condition on the mesh: the nodes are given by a smooth transformation of a square grid and the triangulation is topologically equivalent to a triangulation on this grid by identical triangles, arranged so that six elements surround each internal node. The last requirement leads to the cancellation of error contributions between neighbouring elements; it demonstrates the non-local nature of the Galerkin approximation. In sections 3-5 we simplify the argument somewhat by restricting the mesh further. We take up the more general case in section 6 and predict an alternative superconvergence result which may hold even when the domain of the problem is incompatible with the more relaxed conditions. We do not prove this last result here, but give a numerical demonstration of this and other aspects of superconvergence in section 7.

Separate components of a vector at different points are not what is usually required: we have established superconvergence only for the stress component tangential to the edge on which the sampling point lies. However, if we average the approximate gradient (a piecewise constant vector) between the two elements neighbouring this point, then the interpolant method above indicates that this "recovered" gradient is a superconvergent approximation to both components of the derivative at the stress point. We prove this in Section 3; Lin Qun et al (1983) and Krizč̆ & Neittaanmēki (1983) have obtained restricted forms of this result. There is again a geometrical condition on the mesh: it must obey the restrictions already imposed in sections 3-5. (For the more general meshes of section 6 we must modify the recovery scheme). Finally, we can recover the gradient at an element centroid by averaging recovered values from the three stress points for that element; in section 7 we present a comparison of this scheme with the corresponding superconvergence result on bilinear elements (LeSaint & Zlámal, 1979).
2. **PRELIMINARIES AND TRIANGULATION**

The results of this paper are presented in the context of Sobolev spaces; we introduce here the relevant notation and a key lemma. We work only with bounded open regions in \( \mathbb{R}^2 \) which have the strong cone property (see e.g. Bramble & Hilbert, 1970). Let \( \Omega \) be such a region: typically this will be either the problem domain \( \Omega \) or a small patch of elements. We denote by \( W^m_0(\Omega) \) (\( m = 0, 1, \ldots \)) the Sobolev space of functions which together with their generalised derivatives up to order \( m \) inclusive are in \( L^p_\Omega(\Omega) \). The norm and seminorm are given by

\[
\|w\|_{W^m_0(\Omega)} = \left( \int_{\Omega} \left( \sum_{|\alpha| \leq m} |D^\alpha w|^p \right)^{1/p} \right)^{1/p},
\]

\[
|w|_{W^m_0(\Omega)} = \left( \int_{\Omega} \left( \sum_{|\alpha| = m} |D^\alpha w|^p \right)^{1/p} \right)^{1/p}
\]

respectively for \( p < \infty \), with the usual modification when \( p = \infty \). For the most part we take \( p = 2 \) and write \( H^m, \| \cdot \|_{m, \Omega} \) and \( |\cdot|_{m, \Omega} \) for \( W^m_2 \), \( \| \cdot \|_{W^m_2(\Omega)} \) and \( |\cdot|_{W^m_2(\Omega)} \).

In all that follows the letter \( c \) stands for a generic, positive number, different at each appearance but "constant" in that it is independent of the functions denoted below by \( f, u, v \) or \( w \), the element(s) under consideration and the discretisation parameter \( h \).

**Lemma 2.1** (Simplified form of the Bramble-Hilbert lemma; see Bramble & Hilbert, 1970). Let \( F \) be a linear functional on \( W^m_0(\Omega) \) such that

(i) \( |F(w)| \leq c \|w\|_{W^m_0(\Omega)} \quad \forall w \in W^m_0(\Omega) \)

and (ii) \( F(w) = 0 \) if \( w \) is a polynomial on \( \Omega \) of degree less than \( m \).

Then \( |F(w)| \leq c |w|_{W^m_0(\Omega)} \quad \forall w \in W^m_0(\Omega) \); the constant \( c \) depends on \( F, p, m \) and \( \text{diam}(\Omega) \) only.
We now describe a particular triangulation for which our results hold; the general form is given in section 6. Let Ω be a bounded open domain in \( \mathbb{R}^2 \) with the strong cone property in which \((x,y)\) are rectangular Cartesian co-ordinates. For decreasing values of the parameter \( h \) we triangulate \( \Omega \) in the following way. We choose a pair of functions \((X,Y)\) of \((x,y)\) (and, if necessary, of \( h \)) which can be used as a co-ordinate system on \( \Omega \) and its neighbourhood. (For example, see (7.1) and Fig. 11 below). We require that \((X,Y)\) be smooth in the sense that, uniformly in \( h \), the global mapping \((x,y) \to (X,Y)\) is a \( W^2_\infty \) diffeomorphism with Jacobian satisfying
\[
c^{-1} \leq |\partial(X,Y) / \partial(x,y)| \leq c. \tag{2.1}
\]
Note that the two norms \( \| \cdot \|_{3,\Omega} \) based on \((x,y)\)- and \((X,Y)\)- derivatives are not equivalent. We will make no use of \((X,Y)\)- norms.

We place grid-points on \( \Omega \) so as to give a uniform, square grid in the \((X,Y)\) plane with mesh size \( h \). We triangulate the region in the \((X,Y)\) plane by means of horizontals, verticals and diagonals of slope \(+1\) between the grid points and then in the \((x,y)\) plane with straight lines topologically corresponding to the \((X,Y)\) links. When we refer to elements we will mean the (non-curved) triangles in the \((x,y)\) plane; we call the union of elements \( \Omega_h \). (See Fig. 1).

We require the triangulation to approximate the boundary \( \partial \Omega \) of \( \Omega \) well, in that all the nodes on \( \partial \Omega_h \) lie on \( \partial \Omega \) and the intersection of each element with \( \Omega \) contains an open disk of diameter \( 2h \) of which itself contains the centroid of that element. (It is clear that triangulation functions \((X,Y)\) satisfying all the above conditions do not exist for general regions \( \Omega \); we discuss this problem in section 6).

We denote the elements by \( T_k (k = 1,...,K) \). For each \( k \), let \( N_{k0} = (X_k, Y_k) \) and \( N_{k1} = (X_k + h, Y_k) \) be the nodes with the same \( Y \) co-ordinate (see Fig. 2); let \( N_{k2} \) be the third node. We introduce local co-ordinates
by means of a linear transformation \( t_k \) of \((x, y)\) which maps \( T_k \) onto the triangle \( \tau_k \) and the nodes \( N_{k0}, N_{k1}, N_{k2} \) to \((0, 0), (1, 0)\),
\(
(\xi_{k2}, \eta_{k2}) \) respectively such that
\[
\varepsilon_{k2} \leq c \quad \text{and} \quad c^{-1} \leq \varepsilon(x, y) \leq c \quad \text{(2.2)}
\]

We adopt the notation that functions of \((\xi, \eta)\) are distinguished by a hat from their counterpart functions of \((x, y)\) or \((X, Y)\). Thus \( \hat{w}(\xi, \eta) \)
\( w(t_k^{-1}(x, y)) \), etc.

**Lemma 2.2** Let \( \nabla_m \) denote the tensor of \( m \)th derivatives with respect to
\((X, Y)\) and \( \nabla \) denote gradient with respect to \((x, y)\). The following estimates hold:

(i) \( c^{-1} \leq \varepsilon \leq \varepsilon \leq c \), \( c^{-1} \leq \lambda(t_k) \leq c \);
(ii) each element of the matrix \( \partial(x, y)/\partial(\xi, \eta) \) is bounded in modulus by \( ch \);
(iii) \( |\nabla| \leq c \varepsilon^{-1}, |\nabla_v| \leq c \varepsilon^{-1} \quad (m = 1, 2) \), similarly for derivatives of \( \eta \);
(iv) \( |\hat{w}|_{m, \tau_k} \leq c \varepsilon^{m-1} ||w||_{m, T_k} \quad \forall w \in H^m(T_k) \quad (m = 0, \ldots, 3) \).

**Proofs** These follow from (2.1), (2.2) and the linearity of the \( t_k \). For (iii)
we use \( \partial \xi/\partial x = \partial y/\partial \eta \cdot \det(\partial(\xi, \eta)/\partial(x, y)) \), etc; the \( \varepsilon \) bounds follow
by the chain rule.

There usually exists another triangle, \( T_{k'} \), with the nodes \( N_{k0} \) and \( N_{k1} \)
in common with \( T_k \). We will map \( T_{k'} \) into the \( (\xi, \eta) \) plane with the same
transformation \( t_k \) as \( T_k \) and refer to the quadrilaterals
\( T_k \cup T_{k'} \) and \( \tau_k \cup \tau_{k'} \) as \( A_k \) and \( \alpha_k \) (see Fig. 3). If such a \( T_{k'} \) does not
exist then \( N_{k0} \) and \( N_{k1} \) lie on \( 3\Omega_h \) and we denote \( T_k \) by \( B_k \) (see Fig. 4).

In other words we have the decompositions
\[
\Omega_h = \bigcup_{k=1}^{K_k} T_k = \bigcup_{k=1}^{K_k} A_k \cup \bigcup_{k=1}^{K_k} B_k.
\]

In each \( T_k, A_k \) or \( B_k \), we refer to the midpoint of the edge \( N_{k0} N_{k1} \) as \( M_k \),
(i.e. \( M_k \) is the point \( t_k^{-1}(1, 0) \)). (See Fig. 2).

We now show that each \( \alpha_k \) is close to a parallelogram, in the sense that
the midpoints of its diagonals have separation \( \leq c h \). This lemma is the link
between the triangulation conditions and the superconvergence results that follow.
Lemma 2.3 Let \( k \leq K_A \) be fixed (for convenience we drop the subscript \( k \)) and consider the quadrilateral \( \alpha \), with vertices labelled as in Fig. 3. Then

\[
|\xi_+ + \xi_- - 1| \leq \epsilon \text{ and } |n_+ + n_-| \leq \epsilon.
\]

**Proof** We can view \( \xi \) as a twice differentiable (i.e. \( W^2_\epsilon \)) function of \( (X, Y) \) and consider the functional \( \xi(X_0 + h, Y_0 + h) + \xi(X_0, Y_0 - h) - \xi(X_0 + h, Y_0) - \xi(X_0, Y_0) \). This vanishes for linear \( \xi \) and so the first bound follows from Lemmas 2.1 and 2.2; the second is derived identically.

3. **RECOVERING THE GRADIENT FROM THE INTERPOLANT**

We are now in a position to define interpolation on the mesh and derive some error bounds. Let \( S^h(\Omega_h) \subset H^1(\Omega_h) \) be the space of continuous piecewise linears on the triangulation of \( \Omega_h \). Let \( u \) be any function satisfying \( u \in H^3(\Omega_h) \) (so that \( u \) and \( \nabla u \) are defined everywhere in \( \Omega_h \)). Let \( u_2 \in S^h(\Omega_h) \) interpolate the values of \( u \) at all the nodes of \( \Omega_h \). It is well known that \( |\nabla(u_2 - u)| = O(h) \); since \( u \) can (just) fail to be in \( W^2_\epsilon \), the result takes this form.

**Lemma 3.1** Let \( Q \) be a point in \( T_k \) and let \( \{\cdot\}_Q \) stand for point sampling at \( Q \). Then

\[
|\{\nabla(u_2 - u)\}_Q| \leq c \|u\|_{3, T_k}.
\]

**Proof** Let \( F(u) = \{\nabla(u_2 - u)\}_Q \) and \( \hat{F}(\hat{u}) \) be the corresponding functional-pair on \( H^3(\tau_k) \). When \( u \) is linear on \( T_k \), \( u_2 = u \) and so by Lemma 2.2, the Sobolev Lemma and Lemma 2.1,

\[
|F(u)| \leq ch^{-1}|\hat{F}(\hat{u})| \leq ch^{-1}|\hat{u}|_{W^2_{2+\epsilon}(\tau_k)}
\]

for any fixed \( \epsilon > 0 \). By the Sobolev Lemma again,

\[
|F(u)| \leq ch^{-1}(|\hat{u}|^2_{2, \tau_k} + |\hat{u}|^3_{3, \tau_k})
\]

the result now follows from Lemma 2.2.

Although we use this lemma later, our aim in this section is to suppose we know \( u_2 \) and obtain from it values of \( \nabla u \), correct to \( O(h^2) \). To estimate both
components of this gradient at a single point, we will use the recovery scheme introduced in section 1. Note that if \( v \in S^h(\Omega_h) \) then
\[
\frac{\partial \hat{v}}{\partial \xi} \text{ is constant over } \alpha_k ,
\] (3.1)
this is a constant multiple of the derivative of \( v \) in the direction of the edge common to elements \( T_k \) and \( T_{k'} \). So, for this component of the gradient, our scheme is equivalent to point sampling at \( M_k, \) the midpoint of this shared edge.

For each \( \alpha_k \), we define the recovery operator \( D_k \) on \( S^h(\Omega_h) \) by
\[
D_k (v) = \frac{1}{2} \left( \frac{\partial v}{\partial T_k} + \frac{\partial v}{\partial T_{k'}} \right).
\] (3.2)

**Lemma 3.2** Let \( k \leq K_A \) be fixed (for convenience we drop the subscript \( k \)). Then
\[
|D_{\alpha} - \frac{\partial v}{\partial M}| \leq c \| u \|_{3,A} .
\]

**Proof** Let \( F_1(u) \) and \( F_2(u) \) be the tangential and normal components, respectively, of the recovery error \( D_{\alpha} - \frac{\partial v}{\partial M} \). Then
\[
\hat{F}_1(\hat{u}) = \left[ \frac{\partial \hat{u}}{\partial \xi} \right]_{\alpha} - \left[ \frac{\partial \hat{u}}{\partial \xi} \right]_{(1,0)}
\]
and
\[
\hat{F}_2(\hat{u}) = \frac{1}{2} \left[ \frac{\partial \hat{u}}{\partial \eta} \right]_{\tau_+} + \left[ \frac{\partial \hat{u}}{\partial \eta} \right]_{\tau_-} - \left[ \frac{\partial \hat{u}}{\partial \eta} \right]_{(1,0)},
\]
where \( \tau_+, \tau_- \) are the triangles above and below the \( \xi \)-axis which comprise \( \alpha \) (with vertices labelled as in Fig. 3).

Now,
\[
\begin{align*}
\text{if } \hat{u} = \xi^2 \text{ in } \alpha \text{ then } \hat{u}_I &= \xi + \eta (\xi^2 + \xi_\pm) / \eta_\pm \text{ in } \tau_\pm, \\
\text{if } \hat{u} = \xi \eta \text{ in } \alpha \text{ then } \hat{u}_I &= \eta \xi_\pm \text{ in } \tau_\pm, \\
\text{if } \hat{u} = \eta^2 \text{ in } \alpha \text{ then } \hat{u}_I &= \xi_\pm \text{ in } \tau_\pm.
\end{align*}
\] (3.3)

Also, \( \hat{u}_I = \hat{u} \) for all linear \( \hat{u} \) on \( \alpha \). So, without reference to the mesh geometry, \( \hat{F}_1 \) vanishes for a basis of quadratics on \( \alpha \) (and hence for all quadratics). Therefore, by the Sobolev Lemma and Lemma 2.1
\[
|\hat{F}_1(\hat{u})| \leq c |\hat{u}|_{3,A} .
\] (3.4)
Unfortunately $\hat{F}_2$ is less easy to bound. From (3.3) we have

$$
\hat{F}_2(\xi^2) = \frac{1}{2}(\xi_+^2 - \xi_-^2)/\eta_+ + (\xi_+^2 - \xi_-^2)/\eta_-)
$$

$$
\hat{F}_2(\xi\eta) = \frac{1}{2}(\xi_+^2 + \xi_-^2 - 1)
$$

and

$$
\hat{F}_2(\eta^2) = \frac{1}{2}(\eta_+^2 + \eta_-^2).
$$

If $\alpha$ (or equivalently $A$) were a parallelogram then $\hat{F}_2$ would vanish for quadratic $\hat{u}$ and be bounded exactly as $\hat{F}_1$. However, $\alpha$ is only close to a parallelogram and $\hat{F}_2$ is as a result only close to a functional $\hat{F}_2(\hat{u}_R \hat{u})$ below which vanishes for quadratic $\hat{u}$.

To be precise, let $\hat{R}$ be the projection given by

$$
\hat{R} \hat{u} = \frac{1}{2m(\alpha)} \left[ \xi^2 \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial x^2} + 2\xi\eta \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial x \partial \eta} + \eta^2 \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial \eta^2} \right]
$$

where $m(\alpha)$ is the measure of $\alpha$. Then, by Lemmas 2.2 and 2.3, (2.2) and (3.5),

$$
|\hat{F}_2(\hat{R} \hat{u})| \leq \frac{C}{m(\alpha)} \left[ |\hat{F}_2(\xi^2)| + \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial x^2} + |\hat{F}_2(\xi\eta)| \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial x \partial \eta} \right]
$$

$$
+ |\hat{F}_2(\eta^2)| \int_{\alpha} \frac{\partial^2 \hat{u}}{\partial \eta^2}
$$

$$
\leq C |\hat{u}|_{2,\alpha}.
$$

Also, by the Sobolev Lemma and (3.7),

$$
|\hat{F}_2(\hat{u} - \hat{R} \hat{u})| \leq |\hat{F}_2(\hat{u})| + |\hat{F}_2(\hat{R} \hat{u})|
$$

$$
\leq C (|\hat{u}|_{3,\alpha} + h|\hat{u}|_{2,\alpha})
$$

$$
\leq C |\hat{u}|_{3,\alpha}.
$$

But if $\hat{u}$ is linear, $\hat{R} \hat{u} = \hat{0}$ and $\hat{u}_I = \hat{u}$ (so that $\hat{F}_2(\hat{u} - \hat{R} \hat{u}) = 0$); if $\hat{u}$ is one of $\xi^2$, $\xi\eta$, $\eta^2$ then $\hat{R} \hat{u} = \hat{u}$ and so this functional vanishes for all quadratic $\hat{u}$.

Thus by (3.8) and Lemma 2.1

$$
|\hat{F}_2(\hat{u} - \hat{R} \hat{u})| \leq C |\hat{u}|_{3,\alpha},
$$

whence by (3.7)
\[ |F_2(\hat{u})| \leq c(\hat{|u|}_{3,\alpha} + h|\hat{u}|_{2,\alpha}). \]  \hspace{1cm} (3.9)

Finally, (3.4), (3.9) and Lemma 2.2 give
\[
|Du_I - [Yu]|_M \leq ch^{-1} (|\hat{F}_1(\hat{u})| + |\hat{F}_2(\hat{u})|)
\leq c (h^{-1}|\hat{u}|_{3,\alpha} + |\hat{u}|_{2,\alpha})
\leq c h \|u\|_{3,\alpha} \text{ as desired.}
\]

We now turn to the central question of this paper. Given \( u_h \in S^h(\Omega_h) \) (a finite element approximation to an unknown function \( u \)), how do we estimate \( [Yu] \)? The answer is that since \( X(u_h - u_I) \) is constant over each element, we should use the same recovery procedure with \( u_h \) as with \( u_I \).

**Theorem 3.1** Let \( u \in H^3(\Omega_h) \), \( u_I \in S^h(\Omega_h) \) and \( D_k (k = 1, \ldots, K_A) \) be as above and let \( u_h \) be any member of \( S^h(\Omega_h) \). Then
\[
h \left( \sum_{k=1}^{K_A} |D_k u_h - [Yu]|_M^2 \right)^{\frac{1}{2}} \leq c \left( |u_I - u_h|_{1,\Omega_h} + h^2 \|u\|_{3,\Omega_h} \right).
\]

**Remark** Although this result only bounds recovered derivatives on element edges between nodes with the same \( Y \) co-ordinate (see Fig. 3), it is clear that edges linking nodes with the same value of \( X \) (or \( Y-X \)) can be included in the average. So Theorem 3.1 states that the \( L_2 \) average error of the recovered gradient over all internal edges is bounded by \( |u_I - u_h|_{1,\Omega_h} + O(h^2) \). (The average can also include tangential derivatives at midpoints of edges on \( \partial \Omega_h \).) This comment also applies to Theorems 4.1 and 5.2 below.

**Proof** (Zlamal (1977) has proved a similar result).

By Lemma 2.2 the operators \( D_k \) are bounded thus:
\[
|D_k (v)| \leq ch^{-1} |v|_{1,A_k} \quad \forall v \in S^h.
\]

Squaring and summing,
\[
\sum_k |D_k (v)|^2 \leq ch^{-2} \sum_k |v|_{1,A_k}^2 \leq ch^{-2} |v|_{1,\Omega_h}^2 \quad \forall v \in S^h.
\]
Squaring and summing the result of Lemma 3.2,
\[ \sum_k \| D_k u_I - [\nu u] M_k \|^2 \leq c h^2 \| u \|^2_{3, \Omega_h}. \]

Then, setting \( v = u_I - u_I \) in the above,
\[ \sum_k \| D_k u_h - [\nu u] M_k \|^2 \leq c h^2 \| u_I - u_I \|^2_{1, \Omega_h} + c h^2 \| u \|^2_{3, \Omega_h}, \]
whence the result as required.

4. THE FINITE ELEMENT APPROXIMATION AND NUMERICAL QUADRATURE

From now on, we take \( u \) to be the (unknown) solution to the model problem:
\[ Lu = f \quad \text{in} \quad \Omega, \quad u = g \quad \text{on} \quad \partial \Omega, \]
where \( Lu = -\frac{\partial}{\partial x} \left( a_{11} \frac{\partial u}{\partial x} + a_{12} \frac{\partial u}{\partial y} \right) - \frac{\partial}{\partial y} \left( a_{21} \frac{\partial u}{\partial x} + a_{22} \frac{\partial u}{\partial y} \right) \)

satisfies the classical ellipticity condition and \( a_{12} = a_{21}. \) (We could add the term \( a_0 u \) with \( a_0 \geq 0, \ a_0 \in H^2(\Omega) \) to \( L \) with a straightforward supplementary analysis). The goal of the next two sections is to apply Theorem 3.1 to a finite element approximation \( u_h \) to \( u \) by showing that \( \| u_I - u_h \|_{1, \Omega_h} = O(h^2). \)

We associate with (4.1) the bilinear form on \([H^1(\Omega)]^2\):
\[ a_h(w, v) = \iint_{\Omega} \left[ a_{11} \frac{\partial w}{\partial x} \frac{\partial v}{\partial x} + a_{12} \frac{\partial w}{\partial x} \frac{\partial v}{\partial y} + a_{22} \frac{\partial w}{\partial y} \frac{\partial v}{\partial y} \right] dx \, dy. \]

We will also use the inner product
\[ (w, v, \Omega) = \iint_{\Omega} w v \, dx \, dy. \]

Let \( H^1_E(\Omega) \subset H^1(\Omega) \) be the set whose members satisfy the condition \( w = g \) on \( \partial \Omega \), similarly let \( w = 0 \) on \( \partial \Omega \) for all \( w \in H^1_0(\Omega) \). Then the weak solution of (4.1) is a function \( u \in H^1(\Omega) \) satisfying
\[ a_h(u, v) = (f, v) \quad \forall v \in H^1_0(\Omega); \]
in fact we require the additional smoothness
\[ u \in H^1(\Omega) \cap H^3(\Omega), \quad a_{ij} \in W^2_{2,\epsilon}(\Omega) \quad \text{(i,j = 1,2 for some \( \epsilon > 0 \))} \]
and \( f \in H^2(\Omega) \).
Now, the finite element approximation $u_h$ which we introduce below is defined on $\Omega_h$, which is not necessarily contained in $\Omega$. Although $u_h$ is computed using values of functions on $\Omega$, it will simplify our analysis to extend these functions to $\Omega_h$. Indeed, since $\Omega$ has the strong cone property we can use Calderon's theorem (Calderon, 1961, Theorem 12) to give extensions of $u$ and $a_{ij}$ ($i, j = 1, 2$) in the Sobolev spaces of (4.5) (to $\mathbb{R}^2$ as opposed to $\Omega$). The restriction back to $\Omega$ of the extension operator yields the identity and so we can use a single symbol for a function and its extension. We have

$$\|u\|_{3, \Omega_h} \leq c \|u\|_{3, \Omega} \quad \text{and} \quad \|a_{ij}\|_{W^2_0(\Omega_h)} \leq c \quad (i, j = 1, 2).$$

(4.6)

We extend $f$ as follows:

$$f = L u \in H^1(\Omega_h) \cap H^2(\Omega),$$

(4.7)

where $L$ is the operator of (4.1) and $u$ and the coefficients of $L$ are extended as above. Then by Green's theorem,

$$a_{\Omega_h}(u, v) = (f, v)_{\Omega_h} \quad \forall v \in H^1_0(\Omega_h),$$

(4.8)

where $a_{\Omega_h}(\cdot, \cdot)$ and $(\cdot, \cdot)_{\Omega_h}$ correspond to the forms (4.2) and (4.3) with integration over $\Omega_h$.

In all practical computations, $a_{\Omega_h}(\cdot, \cdot)$ and $(\cdot, \cdot)_{\Omega_h}$ will be evaluated by numerical quadrature. The centroid rule is sufficient for our purposes; its use is denoted thus: $a^*(\cdot, \cdot), (\cdot, \cdot)^*_{\Omega_h}$. (Our results can be modified to apply to any other rule, provided it integrates linear functions exactly in each element).

If $h$ is sufficiently small, the ellipticity of $L$ is passed onto its extension so that (Ciarlet, 1978, Theorem 4.1.2)

$$\|v\|^2_{1, \Omega_h} \leq c a^*_{\Omega_h}(v, v) \quad \forall v \in S^h.$$  

(4.9)

This discrete coercivity condition implies the existence and uniqueness of the finite element approximation which we now define.
Let $S^h_E(\Omega_h)$ be the subset of $S^h(\Omega)$ whose members interpolate nodal values of $g$ on the boundary $\partial \Omega_h$; similarly let $v = 0$ on $\partial \Omega_h$ for all $v \in S^h_0(\Omega_h)$. (Note that $S^h_E(\Omega_h) \not= H^1_E(\Omega_h)$ but $S^h_0(\Omega_h) \subset H^1_0(\Omega_h)$.) We define $u_h \in S^h_E(\Omega_h)$ by

$$a^{*}_{\Omega_h}(u_h,v) = (f,v)^{*} \quad \forall v \in S^h_0(\Omega_h).$$

(4.10)

Also let $u_{i} \in S^h_E(\Omega_h)$ interpolate the values of $u$ at all the nodes of $\Omega_h$. (This corresponds to the $u_{i}$ of section 3, except that $u_{i}$ and therefore $u_{i}$ are no longer "known" functions).

Contributions to $|u_{i} - u_h|_{1,\partial \Omega_h}$ come from a variety of sources; we examine in this section the error due to numerical quadrature. Note that the mesh geometry, i.e. Lemma 2.3, plays no further part until Lemma 5.3.

We expand the numerical approximation to

$$\int_{\Omega_h} w \, dx \, dy \quad \text{in the form}$$

$$\sum_{k=1}^{K} \omega_k G_k \vec{m}(T_k) \quad \text{where} \quad G_k \quad \text{and} \quad \vec{m}(T_k) \quad \text{are the centroid and measure of element} \quad T_k.$$  

We define the local error functional over $T_k$:

$$E_k(w) = \int_{T_k} w \, dx \, dy - [w] G_k \vec{m}(T_k).$$

Lemma 4.1 Let $k$ be fixed (again we drop the subscript). Then

(i) $|E(w)| \leq c h^2 \|w\|_{2,T} \quad \forall w \in H^2(\Omega_h)$

and (ii) $|E(w)| \leq c h^2 \left( \|w\|_{1,T} + \|w\|_{2,\Omega_h} \right) \quad \forall w \in H^1(\Omega_h) \cap H^2(\Omega_h)$.

Proof By (2.2) and Lemma 2.2,

$$|E(w)| \leq c h^2 |\hat{E}(w)|.$$ (4.11)

Since the quadrature scheme is exact for linear $E(w)|$ is not bounded by $\|w\|_{1,T}$. We recall that $T \cap \Omega$ contains an open disk which itself contains the centroid $G$ and whose image, $\tau_*$ say, in the $(\xi,\eta)$-plane has measure $\approx c$ (by (2.2)).

As in Lemma 3.2, we introduce a projection operator:

$$\hat{\Pi} \hat{w} = \left\{ \begin{array}{ll} \frac{\text{meas}(\tau_*)^{-1}}{\int_{\tau_*} \hat{w} \, d\xi d\eta} & \text{in} \quad \tau_* \\ \hat{w} & \text{in} \quad \tau \setminus \tau_* \end{array} \right.$$
Then
\[ \hat{E}(\hat{w}) = \int_{\tau} \hat{w} \, d\xi d\eta - \frac{\text{meas}(\tau)}{\text{meas}(\tau^*)} \int_{\tau^*} \hat{w} \, d\xi d\eta, \]
this is bounded in \( H^1(\tau) \) and vanishes for \( \hat{w} \) constant on \( \tau \). Therefore by the Sobolev Lemma and Lemma 2.1,
\[ |\hat{E}(\hat{w})| \leq c \| \hat{w} \|_{1, \tau} \leq c |\hat{w}|_{1, \tau}. \]
The remainder, \( \hat{E} (\hat{w} - \hat{w}) \) is bounded in \( W^1_{2, e} (\tau^*) \) for fixed \( \varepsilon > 0 \);
it vanishes for \( \hat{w} \) constant on \( \tau^* \) and is thus bounded by \( c(|\hat{w}|_{1, \tau} + |\hat{w}|_{2, \tau^*}) \).
(This is similar to the proof of Lemma 3.1). So
\[ |\hat{E}(\hat{w})| \leq |\hat{E}(\hat{w})| + |\hat{E}(\hat{w} - \hat{w})| \leq c(|\hat{w}|_{1, \tau} + |\hat{w}|_{2, \tau^*}) \]
and (ii) follows from (4.11) and Lemma 2.2.

We apply Lemma 4.1 to give global estimates of the quadrature error:

**Lemma 4.2** Let \( v \in S^h(\Omega_h) \). Then
\[ (f, v)_{\Omega_h} - (f, v)^*_{\Omega_h} \leq c h^2 (\| f \|_{2, \Omega^*} + \| f \|_{1, \Omega_h} + \| v \|_{1, \Omega_h}) \]
and (ii) \( a_{\Omega_h}(u, v) - a_{\Omega_h}^*(u, v) \leq c h^2 \| u \|_{3, \Omega_h} \| v \|_{1, \Omega_h}. \)

**Proof** We again employ a projection method. For (i) we write
\[ |(f, v)_{\Omega_h} - (f, v)^*_{\Omega_h}| \leq \sum_{k=1}^{K} \left( |E_k(f[v])_G_k| + |E_k(f(v-[v])_G_k)| \right). \quad (4.12) \]
To bound the first term when \( T_k \) is wholly contained in \( \Omega \) (so that \( f \in H^2(T_k) \)) we note that
\[ \sup_{T_k} (|v| + |\nabla v|) \leq c^{-1} (|v|_{1, T_k}) \quad \forall v \in S^h \]
(4.13)
and use Lemma 4.1(i) to obtain
\[ |E_k(f[v])_G_k| \leq c h^2 \| f \|_{2, T_k} \| v \|_{1, T_k}. \]
Alternatively \( T_k \) is a boundary element and by Lemma 4.1(ii) (recall (4.7))
\[ |E_k(f[v])_G_k| \leq c h^2 \left( \| f \|_{1, T_k} + \| f \|_{2, T, \Omega} \right) \| v \|_{G_k}. \]
We cannot use (4.13) here without losing an order of \( h \). But since \( v = 0 \) on \( \partial \Omega \),
$$\|v\|_{G_k} \leq c h^{-1} \|v\|_{0,T_k} \leq c |v|_{1,T_k}.$$ 

Therefore, for all $T_k$, 

$$|E_k(f[v]_{G_k})| \leq ch^2 (\|f\|_{1,T_k} + \|f\|_{2,T_k};\Omega) \|v\|_{1,T_k}.$$ 

To bound the other term in (4.12) we write $\gamma_k$ for the centroid of $\tau_k$ and note that since $v$ is linear, $\hat{E}_k = 0$ when $\hat{f}$ is a constant on $\tau_k$. So by (2.2) and Lemmas 2.1 and 2.2, 

$$|E_k(f[v - [v]_G])| \leq ch^2 |E_k(\hat{f}(v - [v])_{\gamma_k})|$$

$$\leq ch^2 \iint_{\tau_k} \hat{f}(v - [v])_{\gamma_k}$$

$$\leq ch^2 \|f\|_{1,T_k} \|v\|_{1,T_k}.$$ 

We now obtain (i) from the above estimates and the Cauchy-Schwarz inequality. 

For (ii) we recall that $\Psi v$ is constant over each element and write 

$$\left| \iint_{T_k} a_{11} \frac{\partial u}{\partial x} \frac{\partial v}{\partial x} - \left[ a_{11} \frac{\partial u}{\partial x} \frac{\partial v}{\partial x} \right]_{G_k} \right| m(T_k)$$

$$\leq E_k \left[ \frac{\partial u}{\partial x} [a_{11}]_{G_k} \right] + E_k \left[ \frac{\partial u}{\partial x} (a_{11} - [a_{11}]_{G_k}) \right] \|\frac{\partial v}{\partial x}\|_{T_k}.$$ 

We bound the first term directly from Lemma 4.1(i); the bound on the second is similar to the corresponding term in (i) above. We use an identical method for the $a_{12}$ and $a_{22}$ terms of $a_{\Omega}(\cdot,\cdot)$ and Cauchy-Schwarz to sum over the elements $T_k$. 

We collect the above results: 

**Theorem 4.1** Let $u, u_h, u_I, f$ and $D_k$ ($k = 1, \ldots, K_A$) be as defined above. Then 

$$h \left( \sum_{k=1}^{K_A} \left| D_k u_h - [\Psi u]_{k} \right|^2 \right)^{\frac{1}{2}} \leq c \sup_{v \in S_h^0} \left| a_{\Omega}^{\ast} (u_I - u, v) \right| \|v\|_{1,\Omega_h}$$

$$+ ch^2 (\|u\|_{3,\Omega} + \|f\|_{2,\Omega}).$$
Proof. If \( \| u_I - u_h \|_{1, \Omega_h} = 0 \) the result follows directly from Theorem 3.1. Otherwise we substitute \( v = u_I - u_h \in S_0^h \) into (4.8) - (4.10). Then by Lemma 4.2,

\[
\| u_I - u_h \|_{1, \Omega_h}^2 \leq c \Omega_h \left( a_h^* (u_I - u_h, v) \right)
\]

\[
\leq c \left( |a_h^* (u_I - u, v)| + |a_h^* (u, v) - a_h^* (u, v)| + |(f, v)_h - (f, v)_h^*| \right)
\]

\[
\leq c \| a_h^* (u_I - u, v) \| + \text{ch}^2 \left( \| u \|_{3, \Omega_h} + \| f \|_{2, \Omega_h^+} \right) \| v \|_{1, \Omega_h}.
\]

By (4.7), \( \| f \|_{1, \Omega_h} \leq c \| u \|_{3, \Omega_h} \) and so

\[
\| u_I - u_h \|_{1, \Omega_h} \leq \frac{c a_h^* (u_I - u, v)}{\| v \|_{1, \Omega_h}} + \text{ch}^2 \left( \| u \|_{3, \Omega_h} + \| f \|_{2, \Omega_h} \right).
\]

The result now follows from Theorem 3.1 and (4.6).

It remains to show that the term \( a_h^* (u_I - u, v) \) is small enough to justify use of the recovery scheme proposed earlier. We devote the next section to this.

5. \( a_h^* (u_I - u, v) = O(h^2) \ \forall v \in S_0^h \)

This bound was derived independently by Oganesian and Ruchovetz (1969), though only for the case of a fully "uniform" grid (i.e. \( X \equiv x \), \( Y \equiv y \)) and without the application to superconvergence. The result here is similar to Lemma 3.2; the principal difference is that the interpolation error

\[ e = u_I - u \]

is now averaged over each \( A_k \) instead of in the neighbourhood of each sampling point \( M_k \). Further complications arise from non-uniformity of the mesh and variability of the coefficients \( a_{ij} \). These are essentially perturbations to the superconvergence effect and we deal with them first.
We use the notation:
\[ b_{11} = a_{11}X_y + a_{12}Y_x, \quad b_{12} = a_{11}Y_x + a_{12}Y_y, \]
\[ b_{21} = a_{12}X_x + a_{22}X_y, \quad b_{22} = a_{12}Y_x + a_{22}Y_y \]
and \[ b = \begin{pmatrix} b_{11} \\ b_{21} \end{pmatrix}. \]

By the chain rule,
\[ \frac{a^*}{\Omega_h}(e,v) = \sum_{k=1}^{K} \left( \sum_{[w]} G_k \right) m(T_k) \tag{5.1} \]
where
\[ w = \begin{pmatrix} \frac{\partial e}{\partial x} b_{11} + \frac{\partial e}{\partial y} b_{21} \\ \frac{\partial v}{\partial x} b_{11} + \frac{\partial v}{\partial y} b_{21} \end{pmatrix} G_k \]

We will examine the first term in (5.1) in detail:
\[ \sum_{k=1}^{K} \left( \frac{\partial v}{\partial x} (b \cdot \Psi_e) \right) G_k \cdot m(T_k) \tag{5.2} \]
considering first the extent to which \( \frac{\partial v}{\partial x} \) differs from the constant \( h^{-1}(\partial v/\partial x_k) \) in element \( T_k \). (Recall \( v \in S_h^0(\Omega_h) \); see Fig. 3).

**Lemma 5.1** Let
\[ S_1 = \sum_{k=1}^{K} \left( \frac{\partial v}{\partial x} G_k - \frac{\partial v}{\partial x} \hat{G}_k \right) \left( b \cdot \Psi_e \right) G_k \cdot m(T_k). \]

Then
\[ |S_1| \leq c h^2 \| u \|_{3, \Omega_h} \| v \|_{1, \Omega_h} \]

Proof. Consider a single element \( T_k \). (As before we drop the subscript \( k \)).

In this element,
\[ \frac{\partial \hat{v}}{\partial x} = h \frac{\partial v}{\partial x} + F(X) \frac{\partial v}{\partial x} + F(Y) \frac{\partial v}{\partial y} \tag{5.3} \]

where
\[ \hat{\Psi}(\xi) = \frac{\partial}{\partial \xi} - \left[ \Psi \right]_{(1,0)} + \left[ \Psi \right]_{(0,0)} \]

\((\hat{X}, \hat{Y})\) are viewed as functions of \((\xi, \eta)\) (hence the \( \hat{\cdot} \)) and everything is evaluated at some fixed point \((\xi, \eta) = t(\overline{X}, \overline{Y})\) unless otherwise stated. (Recall that if \((\hat{X}, \hat{Y})(0,0) = (X_0, Y_0)\) then \((\hat{X}, \hat{Y})(1,0) = (X_0 + h, Y_0)\).
Now if $\hat{X}$ is linear in $(\xi, \eta)$ then $\hat{F}(\hat{X}) = 0$. So by the Sobolev Lemma and Lemmas 2.1 and 2.2,

$$|\hat{F}(\hat{X})| \leq c h^2 |X|^2_{W^2_0(T)} \leq ch^2. $$

Similarly $|\hat{F}(\hat{Y})| \leq ch^2$ and (5.3) becomes

$$\left| \left[ \frac{\partial v}{\partial x} \right] \frac{1}{(x, y)} \right| \leq h^{-1} \sup_{(X, Y) \in (x, y) \in \mathbb{C}} \left| \hat{F}(\hat{X}) \frac{\partial v}{\partial X} + \hat{F}(\hat{Y}) \frac{\partial v}{\partial Y} \right|$$

$$\leq c \sup_T |v|$$

$$\leq c \|v\|_{1, T}^2. $$ (5.4)

We sum over $k$. By Lemmas 2.2 and 3.1 and Cauchy-Schwarz,

$$|S_1| \leq \sum_{k=1}^K h^{-1} \frac{\partial v}{\partial X_{G_k}} \cdot \frac{\partial v}{\partial X_{G_k}} \cdot \|b\|_{G_k} \cdot \|v\|_{G_k} \cdot m(T_k)$$

$$\leq \sum_{k=1}^K c \|v\|_{1, T_k} \cdot c \|u\|_3 \cdot c \cdot ch^2$$

$$\leq ch^2 \|u\|_{3, \Omega_h} \|v\|_{1, \Omega_h}.$$

The next step is to bound the variation of $b$ over each element.

Recall $M_k$ ($k = 1, \ldots, k$) are the stress points (as in Fig. 2).

**Lemma 5.2** Let

$$S_2 = \sum_{k=1}^K h^{-1} \frac{\partial v}{\partial X_{G_k}} \cdot \frac{\partial v}{\partial X_{M_k}} \cdot \|b\|_{G_k} \cdot \|v\|_{G_k} \cdot m(T_k).$$

Then

$$|S_2| \leq c h^2 \|u\|_{3, \Omega_h} \|v\|_{1, \Omega_h}.$$

**Proof** Again, we consider a single element, $T_k$, and drop the subscript $k$.

We denote by $Z$ the matrix whose $(i, j)^{th}$ element is $a_{ij}$ and write

$$[b]_G - [b]_M = \frac{1}{2} \left( ([Z]_G + [Z]_M)(([\nabla X]_G - [\nabla X]_M)ight.$$

$$+ ([Z]_G - [Z]_M)(([\nabla X]_G + [\nabla X]_M)).$$
Now $X \in W_{\infty}^2$ and each element of $Z$ is in $W_{2+\varepsilon}^2$. Therefore both $|Z|_{W_{\infty}^1(T)}$ and $|\nabla X|_{W_{\infty}^1(T)}$ are bounded and we obtain

$$|[b]_G - [b]_M| \leq ch$$

from Lemmas 2.1 and 2.2. Furthermore, from (5.4) we have

$$|\partial \hat{v}/\partial \xi| \leq c \|v\|_{1,T}.$$ 

The result now follows directly from Lemmas 2.2 and 3.1 and Cauchy-Schwarz.

For the next result we recall (3.1) and group the elements into triangle pairs $A_k$, rewriting numerical quadrature of $\hat{v}_e$ as a functional-pair:

$$F_k(u) = [\hat{v}_e]_{G_k} m(T_k) + [\hat{v}_e]_{G_{k'}} m(T_{k'}) \quad (k = 1, \ldots, K_A).$$

**Lemma 5.3** Let

$$S_3 = \sum_{k=1}^{K_A} h^{-1} \left[ \frac{\partial \hat{v}}{\partial \xi} \right]_{T_k} [b]_{M_k} \cdot F_k(u).$$

Then

$$|S_3| \leq ch^2 \|u\|_{3,\Omega_h} \|v\|_{1,\Omega_h}.$$ 

**Proof** This is essentially the same as that of Lemma 3.2. We fix $k$ initially, dropping the subscript. As before we write $\tau_+$, $\tau_-$ for the triangles with vertices $\{(1,0), (0,0), (\xi_+, \eta_+)\}, \{(0,0), (1,0), (\xi_-, \eta_-)\}, \{(1,0), (0,0), (\xi_+, \eta_+)\}$, with $\tau_+ \cap \tau_- = \alpha$. (See Fig. 3). Then the relations (3.3) hold and we have

$$\hat{F}(\xi^2) = \begin{cases} 1/6 ((2\xi_- - 1)\eta_+ - (2\xi_+ - 1)\eta_-) \\ 1/2 (\xi_-(1 - \xi_+) - \xi_+(1 - \xi_-)) \end{cases}$$

and

$$\hat{F}(\eta^1) = \begin{cases} 1/6((\eta_- - \eta_+)^2) \\ 1/6((1 - 2\xi_-)\eta_+ - (1 - 2\xi_+)\eta_-) \end{cases}$$

and

$$\hat{F}(\eta^2) = \begin{cases} 0 \\ 1/6((\eta_-^2 - \eta_+^2) \end{cases}$$

(5.5)

If $\alpha$ were a parallelogram $\hat{F}$ would vanish for quadratic $\hat{v}$. But $\alpha$ is only close to a parallelogram, so we recall the projection $\hat{R}$ of (3.6) and, exactly as in Lemma 3.2, use (5.5) to obtain
\[ |\hat{F}(\hat{u})| \leq c |\hat{u}|_{2,\alpha} \]

and
\[ |\hat{F}(\hat{u} - \hat{\hat{u}})| \leq c |\hat{u}|_{3,\alpha} \].

So by Lemma 2.2
\[ |\hat{F}(u)| \leq c h |\hat{F}(u)| \leq c h^3 \|u\|_{3,\Omega} \]

and the result is obtained, as in the last two lemmas, by summing over \( k \).

We now complete the superconvergence proof with:

**Theorem 5.1** Let \( u \) and \( u_I \) be as defined and let \( v \in S_0^h(\Omega_h) \).

Then
\[ |a_\Omega^* (u_I - u, v)| \leq c h^2 \|u\|_{3,\Omega} \|v\|_{1,\Omega} \]

**Theorem 5.2** As an immediate consequence of (4.6) and Theorems 4.1 and 5.1,
\[ h \left( \sum_{k=1}^{K_h} \left| D_{\Omega} u_h \frac{\partial}{\partial k} \right|_{M_k} \right)^{1/2} \leq c h^2 \left( \|u\|_{3,\Omega} + \|f\|_{2,\Omega} \right). \]

Proof of Theorem 5.1 We note that \( \partial v / \partial \epsilon_k = 0 \) in each \( B_k \). For (see Fig. 4) in every \( B_k \) the nodes \( N_{k0} \) and \( N_{k1} \) lie on \( \partial \Omega \). But \( v \in S_0^h(\Omega_h) \) and so \( v = 0 \) at \( N_{k0} \) and \( N_{k1} \) and varies linearly between them. Hence the component of \( \nabla v \) parallel to \( N_{k0} N_{k1} \) is zero.

Therefore by lemmas 5.1 - 5.3,
\[ \sum_{k=1}^{K_h} a_{\Omega}^* \left( \frac{\partial v}{\partial k} \right) \sum_{k=1}^{K_h} m(T_k) \left| a_{\Omega}^* \frac{\partial v}{\partial k} \right| \leq c h^2 \|u\|_{3,\Omega} \|v\|_{1,\Omega} \]

Returning to (5.1), we have bounded the first term; the second is bounded similarly. We have now derived \( L_2 \) superconvergence of the recovered gradient at element edge midpoints.
6. THE MESH GEOMETRY

In this section we relax the triangulation conditions of section 2, but on
general curved regions Ω we do not then expect superconvergence in the global
sense of sections 3-5. For these cases we propose a local form of the superconvergence
property.

We refer to any region for which Theorem 5.2 holds (∀u ∈ H^3(Ω), f ∈ H^2(Ω)) as
"superconvergent". For example, it is clear that this includes any region whose
topologically equivalent triangulation in the (X,Y) plane is the mesh shown in
Fig. 5(a).

The region shown in Fig. 5(b) does not satisfy the triangulation specifications:
however with a modified recovery scheme it is superconvergent. This property is true
for all (sufficiently smooth) meshes with exactly six elements meeting at each
internal node. We call then "chevron meshes" (Fig. 6); their definition is
sufficient to ensure that Ω̄_h can be exactly partitioned into "bands" of
triangles. A "band" consists of one or more adjacent, entire columns (or
rows) of the squares which make up the triangulation Ω̄_h, plus any left-over
triangles (B_k) at the two ends (i.e. on ∂Ω̄_h). Ω is triangulated as before,
except that all the diagonals in a band may have (X,Y)-slope -1 instead of +1.

This generalisation affects only two stages of the superconvergence proofs
in the previous sections. We recall that Lemma 5.3 requires the sum (5.1)
to be partitioned into two terms. The first term (5.2) has as a factor the component
of V̂v which is (almost) constant over triangle pairs with common edge (almost)
parallel to the X-axis - see Lemma 5.1 - similarly for the second term and the
Y-axis. It is this partition which we modify here, dealing with each band
separately. We consider without loss of generality a region Ω with band-boundaries
(almost) parallel to the X-axis (as in Fig. 6) and a band for which each
hypotenuse has (X,Y)-slope ±1; instead of (5.1) we write
\[ w = \left( \frac{\partial w}{\partial x} b_{11} + \frac{\partial w}{\partial y} b_{21} \right) \left( \frac{\partial v}{\partial x} b_{12} \pm \frac{\partial v}{\partial y} b_{22} \right) \frac{\partial v}{\partial y} \]  

(6.1)

Now \((\partial v/\partial x \pm \partial v/\partial y)\) is (almost) constant over triangle pairs with common edge of slope \(\pm 1\), i.e. over the squares which comprise the band. Therefore there are no unpaired triangles \(b_k\) on the "long" edges of the band (internal to \(\Omega_h\)) on which \(v=0\) is not guaranteed. So with the decompositions (6.1) we can write \(a^*_h(e,v)\) as a sum of contributions from each band and Theorem 5.1 proceeds as before.

The other aspect of superconvergence which is sensitive to mesh geometry is the recovery of the stress component normal to element edges. The tangential component (recall the bounding of \(\hat{F}_1\) in Lemma 3.2) is not affected. So Theorem 5.2 holds for all chevron meshes, if we remove from the average those normal stress components which are directed through band-boundaries. We can, however, recover the full stress at these points by means of a modified scheme: we average the gradient over four elements, as shown in Fig. 7. The resulting error of this well-centred difference scheme is bounded analogously to Lemma 3.2; we conclude that with this new recovery scheme all chevron meshes are superconvergent.

We note here that the criss-cross mesh (see Fig. 8) required for derivative superconvergence in the mixed method of Fix et al. (1981) does not have six elements surrounding each node and cannot be arranged into bands. So (this is independent of the choice of recovery scheme) Lemma 5.3 cannot be applied; the mesh is not superconvergent. It is because of this necessary restriction that no rectangular mesh on an octagonal region is superconvergent (Fig. 9(a)). This case is qualitatively equivalent to the mesh shown in Fig. 9(b) where we obtain at best \(|a^*_h(e,v)| = O(h^{3/2})\). This \(O(h^{3/4})\) drop in accuracy is confirmed numerically in section 7.

We conclude that, with the introduction of chevron meshes, the conditions for superconvergence can be satisfied on a wide variety of practical problem domains.
We are, however, still a long way from superconvergence on general regions; there is a theoretical barrier (the "six element" condition) to further progress. In the next section we present evidence supporting an alternative result: that superconvergence holds in those subregions of $\Omega_h$ which are bounded away from areas where the mesh conditions (or, for example, the smoothness of $u$) break down. A proof of this, combining sections 3-5 above with approximation properties of Green's functions (Rannacher & Scott, 1982) is in preparation. It is expected that this new result will give pointwise superconvergence, i.e. without the need (as in e.g. Theorem 5.2) to take an $L^2$ average over the stress points.

7. NUMERICAL RESULTS

(i) Centroid Recovery

The recovery scheme considered above is that of averaging the approximate gradient between neighbouring elements; this yields an $O(h^2)$ estimate of the true gradient at the midpoint of the shared edge. We denote the $L^2$ error of this recovery scheme (averaging over all possible edges) by $E_{\text{mid}}$. A simpler though generally less useful procedure is to sample just the tangential component of the gradient at the midpoint of each element edge; this is an $O(h^2)$ estimate of that component of the true gradient. We denote this $L^2$ average error by $E_{\text{tgt}}$.

We can also recover the gradient at the centroids, simply and to $O(h^2)$: we first recover the gradient at the midpoint of each of the edges of a triangle and then average these three gradients to obtain an approximation to the gradient at the centroid. (To prove that this scheme leads to superconvergence we either regard it as the result of a linear fit to the recovered gradient at these three stress points or make a straightforward change to Lemma 3.2). We then have a weighted averaging scheme between four elements (see Fig. 10); we denote the $L^2$ average error by $E_{\text{rec}}$.

We now recall the claim that the gradient can be sampled to high accuracy at the centroid of each element. That this cannot be to $O(h^2)$ follows simply from Theorem 5.2 and Taylor's Theorem (for details see Levine, 1982). We denote
the $L_2$ average error for this sampling procedure by $E_{\text{cent}}$.

To compare these four measures of error, we considered Poisson's equation on the unit square, $\Omega = (0,1) \times (0,1)$, with exact solution

$$u = x(1-x)y(1-y)(1+2x+7y).$$

We triangulated $\Omega$ with a uniform mesh separation $(x \equiv X, y \equiv Y)$ taking successively $h = \frac{1}{4}, \frac{1}{6}, \frac{1}{8}, \frac{1}{10}, \frac{1}{12}$. We set $f = -\Delta u$ on $\Omega$ and $g = u$ on $\partial\Omega$ and solved (4.10) to obtain $u_h$ for each $h$. We found that each error was within 10% (and usually 5%) of its asymptotic rate for $h \leq \frac{1}{6}$; these rates were

$$E_{\text{tgt}} = 1.4h^2,$$

$$E_{\text{mid}} = 3.0h^2,$$

$$E_{\text{rec}} = 3.0h^2$$

and

$$E_{\text{cent}} = 1.2h.$$

Remarks

(a) The same problem has been solved with bilinear elements, where sampling at
centroids leads to superconvergence. Le Saint & Zlamal (1979) gave the result $E_{\text{cent}} = 0.91h^2$.

(b) To investigate the error introduced by numerical quadrature we solved the above
problem using exact integration instead of the centroid rule. Only a slight
improvement occurred ($E_{\text{rec}} = 2.8h^2$).

(c) We solved this problem using the cross-cross mesh (Fig. 6) for which super-
convergence is not expected (under any recovery scheme). We obtained

$$E_{\text{rec}} = 0.45h$$

and

$$E_{\text{cent}} = 1.0h,$$

indicating that there may be some value in using the recovery algorithm even when
superconvergence is absent.

(d) We considered a curved mesh, distorting $\Omega$ into the sector shown in Fig. 11
by the transformation

$$x = (X + 2)/(1 + Y^2/4)^{\frac{1}{2}} - 2,$$

$$y = Y(1 + x/2).$$

(7.1)
Superconvergence was again observed, with

\[ E_{\text{tgt}} = 1.2h^2 \]
\[ E_{\text{mid}} = 3.2h^2 \]
\[ \text{and} \quad E_{\text{rec}} = 3.0h^2. \]

(ii) **Local Superconvergence**

We took \( \Omega \) to be the truncated unit square triangulated as in Fig. 9(b), \( h = \frac{1}{4}, \ldots, \frac{1}{12} \) and solved (4.10) for Poisson's equation as above, with exact solution

\[ u = (x-1)^2 + y^2. \]

(This is a function for which there is zero error on uniform superconvergent triangulations. We chose it to highlight asymptotic behaviour for computationally reasonable values of \( h \). It has been our experience that when breakdown of superconvergence is due to effects from a subdomain of \( \Omega \), such as the neighbourhood of a line, the error is somewhat smaller than expected and the asymptotic rate is not attained for practical values of \( h \).)

As expected, we obtained

\[ E_{\text{rec}} = 1.9h^{3/2} \]
\[ \text{and} \quad E_{\text{cent}} = 0.47h. \]

However, when we restricted the averages to elements in the subdomain \((0, \frac{1}{3}) \times (0, \frac{1}{3})\) (this is bounded away from the region where the mesh conditions break down) we obtained

\[ E_{\text{rec}} = 1.9h^2 \]
\[ \text{(and} \quad E_{\text{cent}} = 0.47h). \]

This is the local superconvergence effect predicted in the last section. Its implication, which is of practical significance, is that for any \( \Omega \) there exists a series of triangulations such that our superconvergence results hold in all elements bounded away from \( \partial \Omega \).
ACKNOWLEDGEMENTS

I would like to thank Professor K.W. Morton for invaluable discussions,
Paul Samuels for the use of his finite element code and the Science & Engineering
Research Council and the University of Reading for their financial support.
